

- Create a base class `Animal` with a method `sound()`. Create a derived class `Dog` that overrides the `sound()` method. Demonstrate method overriding.
- Create class `A` with method `show()`. Create class `B(A)` that overrides `show()` and also calls the parent method using `super()`.
- Create multi-level inheritance with classes `A → B → C`, each having a method `display()` printing the class name. Create object of `C` and call `display()`, showing method resolution.
- Implement hierarchical inheritance using a base class `Vehicle` and two child classes `Car` and `Bike`, each defining a method `wheels()`.
- Create class `Employee` with an instance method `salary()`. Create class `Manager(Employee)` that overrides `salary()` and adds an incentive. Demonstrate both outputs.
- Create class `University` with a class variable and a class method. Inherit it into class `College` and access the parent's class variable from the child class.
- Create class `MathOps` with a static method `add(a, b)`. Create class `AdvancedOps(MathOps)` and use the static method without overriding it.
- Create two classes `Father` and `Mother`, both defining a method `skills()`. Create class `Child(Father, Mother)` and check which `skills()` runs using MRO.
- Create an abstract class `Shape` with an abstract method `area()`. Create class `Rectangle(Shape)` that implements the `area()` method.
- Create class `Person` with a constructor `__init__(name)`. Create class `Student(Person)` with constructor `__init__(name, roll)`. Use `super()` to call the parent constructor.
