• Write a Python program using a context manager (with) to open a text file in read mode, read the entire content using read(), and print the number of characters in the file.

• Write a program that opens a file using a context manager, reads all lines using readlines(), and prints only the lines that contain more than 10 characters.

• Write a program that creates a file and writes 3 lines using write(), reopens the same file in append mode, appends 2 more lines, and finally reads and prints the complete file content.

• Write a program that opens a file in read mode, reads the first 10 characters, prints the current cursor position using tell(), moves the cursor back to the beginning using seek(0), and reads the full content again.

• Create a custom context manager using a class that opens a file in write mode in the __enter__ method, writes a line to the file, closes the file in the __exit__ method, and properly prints or logs any exception information received in __exit__.

• Create a custom context manager using @contextmanager from the contextlib module that opens a file, yields the file object, and ensures the file is closed even if an exception occurs.

• Write a program using a context manager that opens a file in read mode, uses a loop to read the file in small chunks (for example, 5 characters at a time), prints the cursor position after each read using tell(), uses seek() to move to a specific position, and continues reading from there.
